RFC-005: Progressive Metadata Levels

Status: Implemented **Date:** January 2026 **Author:** Derrell Piper ddp@elud om.net **Implementation:** vault.scm (seal-commit, save-commit-metadata)

Abstract

This RFC specifies progressive metadata levels for vault commits, enabling configurable richness from minimal overhead to full preservation context. Three levels serve different use cases: minimal (fast iteration), catalog (discovery), and preserve (archival).

Motivation

Different commits deserve different metadata:

- **Quick fix**: Just record it happened
- **Feature release**: Add searchable keywords
- **Archival snapshot**: Capture full environment

Traditional VCS provides one-size-fits-all commit messages. Cyberspace provides progressive levels:

1. **Minimal** - Hash, timestamp, message (default)
2. **Catalog** - Add subjects, keywords, descriptions (discovery)
3. **Preserve** - Add environment, dependencies, git state (archival)

Specification

Level 1: Minimal (Default)

Every commit includes:

```
(commit-metadata
  (hash "abc123...")
  (timestamp 1767685100)
  (message "Fix typo in README"))
```

Usage:

```
(seal-commit "Fix typo in README")
```

This is the default. No extra flags needed. Git handles storage.

Level 2: Catalog

Adds discovery metadata:

```
(commit-metadata
  (hash "def456...")
  (timestamp 1767685200)
  (message "Implement user authentication")
  (catalog
    (subjects "authentication" "security")
    (keywords "login" "oauth" "jwt")
    (description "Added OAuth2 authentication flow with JWT tokens")))
```

Usage:

```
(seal-commit "Implement user authentication"
  catalog: #t
  subjects: '("authentication" "security")
  keywords: '("login" "oauth" "jwt")
  description: "Added OAuth2 authentication flow with JWT tokens")
```

Purpose: Enable search and categorization without full environmental capture.

Level 3: Preserve

Adds archival metadata:

```
(commit-metadata
  (hash "789abc...")
  (timestamp 1767685300)
  (message "Release v2.0.0")
  (preservation
    (environment
      (platform "darwin")
      (hostname "dev-machine")
      (chicken-version "5.x")
      (timestamp 1767685300))
    (dependencies
      (egg "srfi-1" "1.0")
      (egg "crypto-ffi" "0.1"))
    (git-state
      (branch "main")
      (remote "git@github.com:ddp/cyberspace.git"))))
```

Usage:

```
(seal-commit "Release v2.0.0"
  preserve: #t)
```

Purpose: Capture everything needed to understand and reproduce the commit environment.

Metadata Fields

Catalog Fields

Field	Type	Description
subjects	list	Library of Congress style subject headings
keywords	list	Free-form search terms
description	string	Extended description (beyond commit message)

Preservation Fields

Field	Type	Description
environment.platform	string	OS type (darwin, linux, etc.)
environment.hostname	string	Machine name
environment.chicken-version	string	Scheme implementation version
environment.timestamp	integer	Unix epoch seconds
dependencies	list	Installed eggs/libraries
git-state.branch	string	Current branch
git-state.remote	string	Remote URL

Storage

Metadata stored in `.vault/metadata/`:

```
.vault/
  metadata/
    abc123.sexp
    def456.sexp
    789abc.sexp
```

Filename is commit hash. Content is S-expression metadata.

Optional Git Tracking

```
(vault-config 'track-metadata #t)
```

When enabled, metadata files are staged for the next commit, creating a self-documenting archive.

Implementation

save-commit-metadata

```scheme
(define (save-commit-metadata commit-hash
          #!key message catalog subjects keywords description preserve)
  "Save optional metadata for a commit"
  (create-directory ".vault/metadata" #t)

  (let ((metadata-file (sprintf ".vault/metadata/~a.sexp" commit-hash)))

    ;; Build metadata structure
    (let ((metadata (list 'commit-metadata
                          (list 'hash commit-hash)
                          (list 'timestamp (current-seconds))
                          (list 'message message))))

      ;; Add catalog if requested
      (when (or catalog subjects keywords description)
        (set! metadata (append metadata (list (build-catalog ...)))))

      ;; Add preservation if requested
      (when preserve
        (set! metadata (append metadata (list (build-preservation ...)))))

      ;; Write metadata file
      (with-output-to-file metadata-file
        (lambda ()
          (write metadata)
          (newline))))))
```

Environment Capture

```scheme
(define (get-environment-snapshot)
  "Capture current build environment"
  `((platform ,(or (get-environment-variable "OSTYPE") "unknown"))
    (hostname ,(or (get-environment-variable "HOSTNAME") "unknown"))
    (chicken-version "5.x")
    (timestamp ,(current-seconds))))

(define (get-dependencies-snapshot)
  "Capture current dependencies"
```

```
  ;; Could scan imports, check installed eggs
  '())

(define (get-git-state-snapshot)
  "Capture git repository state"
  (let ((branch (with-input-from-pipe "git branch --show-current" read-line))
        (remote (with-input-from-pipe "git remote -v" read-line)))
    `((branch ,branch)
      (remote ,remote))))
```

Use Cases

Daily Development (Minimal)

```
(seal-commit "WIP: refactoring auth module")
(seal-commit "Fix off-by-one error")
(seal-commit "Update dependencies")
```

Fast, lightweight, no overhead.

Feature Completion (Catalog)

```
(seal-commit "Add two-factor authentication"
  catalog: #t
  subjects: '("authentication" "security" "2FA")
  keywords: '("totp" "authenticator" "login")
  description: "Implements TOTP-based 2FA per RFC 6238")
```

Enables later discovery: "find all commits about authentication"

Release Snapshot (Preserve)

```
(seal-commit "Release v2.0.0"
  preserve: #t)
```

Captures full environment for reproducibility and forensics.

Query Support

Future enhancement: query interface for metadata.

```
;; Find by subject
(vault-search subjects: '("authentication"))

;; Find by keyword
(vault-search keywords: '("oauth"))
```

```scheme
;; Find by date range
(vault-search from: "2026-01-01" to: "2026-01-31")

;; Find with preservation data
(vault-search has-preservation: #t)
```

Security Considerations

Information Leakage

Preservation metadata captures: - Hostname (could reveal infrastructure) - Platform (could reveal vulnerabilities) - Dependencies (could reveal attack surface)

Recommendation: Use preserve level only for internal archives. Strip when publishing externally.

Metadata Integrity

Metadata files are not automatically signed. For tamper-evidence: 1. Enable `track-metadata` to include in commits 2. Use seal-release for cryptographic sealing 3. Audit trail captures metadata operations

---

Design Rationale

Why Not Always Full Metadata?

1. **Performance**: Environment capture adds latency
2. **Noise**: Not every commit needs forensic detail
3. **Privacy**: Some metadata reveals sensitive info
4. **Storage**: Full metadata increases repository size

Why S-expressions?

1. **Readable**: Human-inspectable without tools
2. **Parseable**: Machine-processable
3. **Extensible**: Add fields without schema changes
4. **Native**: Scheme can read/write directly

Why Separate Files?

1. **Git-friendly**: Small files diff well
2. **Query-friendly**: Can glob/grep metadata
3. **Optional**: Metadata doesn't bloat git objects
4. **Flexible**: Can delete without rewriting history
